

Problem 1

System works if at least 11 components work.

Simulation:

$$\sum_{i=1}^{15} I(U_i \leq p_i) \geq 11$$

a)

analytical

$$1 + \sum_{i=0}^{10} -\binom{15}{i} 0.1^{15-i} 0.9^i = 0.987$$

simulation results:

$$P(\text{System works}) = 0.987$$

b)

with probabilities: .9, .9, .7, .8, .8, .7, .9, .7, .7, .8, .8, .7, .9, .8, .9, .8

```
p <- c( .9, .9, .7, .8, .8, .7, .9, .7, .7, .8, .8, .7, .9, .8, .9, .8 )
n <- 1e6
u.mtx <- matrix( runif( n=n*15 ), ncol=15 )
f.matrix <- ( u.mtx < matrix( rep( p, times=n ), byrow=T, ncol=15 ) )
y.f <- rowSums(f.matrix)
sum( y.f >= 11 )/n.replic
sd(y.f >= 11) / sqrt(n.replic);
```

simulation results: $P(\text{System works}) = 0.841$ with standard error = 0.00366

Problem 2

a)

ref [1]

$$g(x) = 4\sqrt{1-x^2}dx$$

$$\int_0^1 g(x) = \pi$$

$$E(3\sqrt{1-U^2}) = \pi, U \sim U[0, 1]$$

$$\frac{1}{n} \sum_{i=1}^n 4\sqrt{1-U_i^2}$$

$$\frac{4}{n} \sum_{i=1}^n \sqrt{1-U_i^2} \rightarrow E(4\sqrt{1-U^2}) = \int g(x)f(x)$$

where $f(x)$ is the density function $\frac{1}{b-a} = \frac{1}{1-0}$

$$4 \int_0^1 \sqrt{1-x^2} = 4 \left[\frac{1}{2} (\sqrt{1-x^2} x + \sin^{-1}(x)) \right]_0^1 = 4 * \frac{1}{2} \frac{\pi}{2} = \pi \quad Q.E.D$$

and:

$$\text{Var}(4\sqrt{1-U^2}) = 32/3 - \pi^2$$

$$\text{Var}(X) = E(X^2) - (E(X))^2$$

$$(E(g(x)))^2 = \pi^2 \text{ from previous}$$

$$E(g(x)^2) = 16 \int_0^1 \sqrt{1-U^2}^2 = 16 \int_0^1 1-U^2$$

$$= 16[U - \frac{U^3}{3}]_0^1 = 16[0 - (1 - \frac{1}{3})] = 16 - (1 - \frac{1}{3})$$

$$\text{Var}(4\sqrt{1-U^2}) = (16(1 - \frac{1}{3})) - \pi^2 = (16 - \frac{16}{3}) - \pi^2 = \frac{32}{3} - \pi^2 \quad Q.E.D$$

b)

```
U <- runif(1e6)
theta.hat <- mean(4*sqrt(1-U^2))
theta.hat
> [1] 3.14041
```

Problem 3

a)

```
lambda <- 2;
t0 <- 20; #intervall [0:20]
Tn <- rexp(100, lambda) # interarrival times with 100 observations
Sn <- cumsum(Tn) # arrival times
n <- min(which(Sn > t0)) # arrivals+1 in [0 , t0=20]
```

b)

$$E(N(5)) = 9.983, SD(N(5)) = 3.157$$

$$E(N(20)) = 40.001, SD(N(20)) = 6.320$$

mean is calculated by taking the mean of the values from the arrivals vector in R
standard deviation is calculated the same way by using sd(); function

The values should be approaching $E(N(k)) = k * \lambda$ when the number of runs of code from a) is big enough, where k is 5 and 20 in our case.

e.g. $E(N(5)) = \lambda * 5 \sim approx = 9.983$.

c)

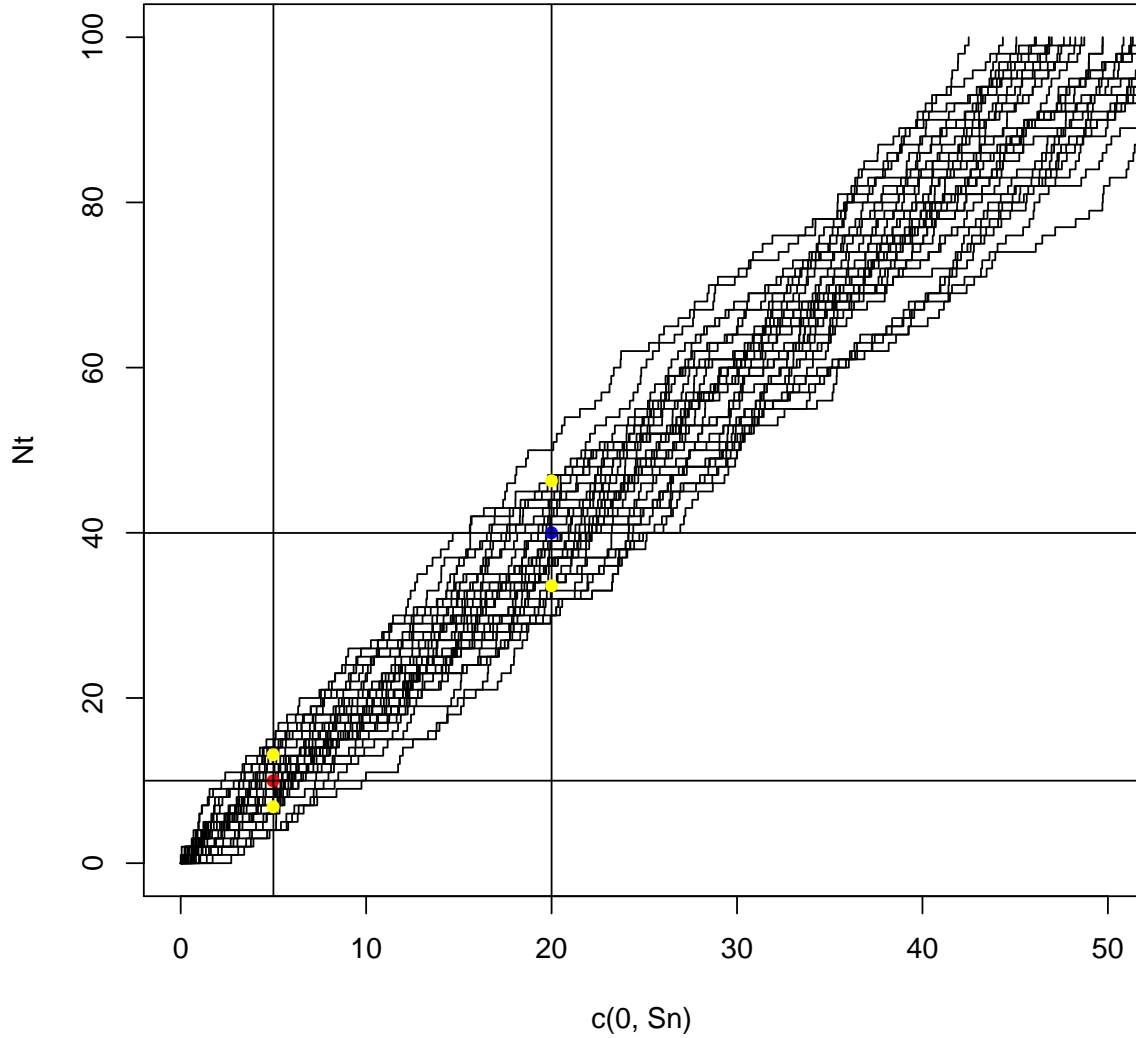

Figure 1: 30 indepentant realizations of poisson process with $\lambda = 2$

The red point shows the $E(N(5))$ and the blue point shows $E(N(20))$ which correspond nicely with the graph.

As for the standard deviation we can notice that it gets bigger when t_0 gets bigger, and this is also visible on the graph with 30 instances, it gets spread out more as the number of observations increase.

Problem 4

a)

T_1 and T_2 are exponentially distributed with mean 1 becuse we are drawing from uniform distribution $U \sim U[0, 1]$ and using inverse transform sampling. ref [1]

b)

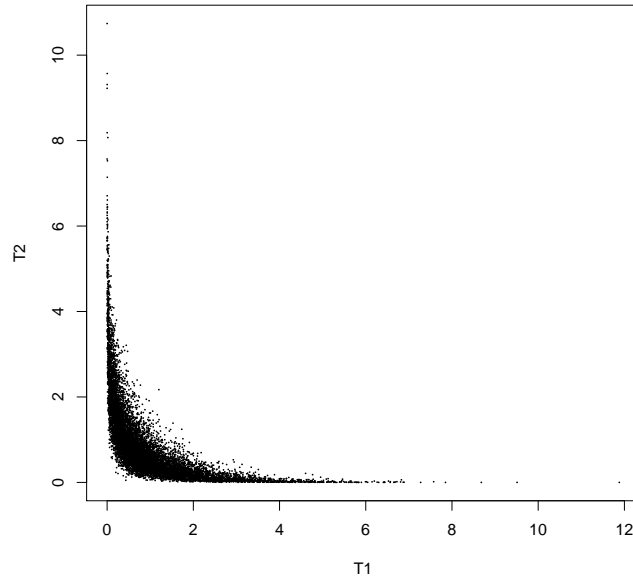

Figure 2: Scatter plot of T_1 vs T_2 with $\rho = -0.9$

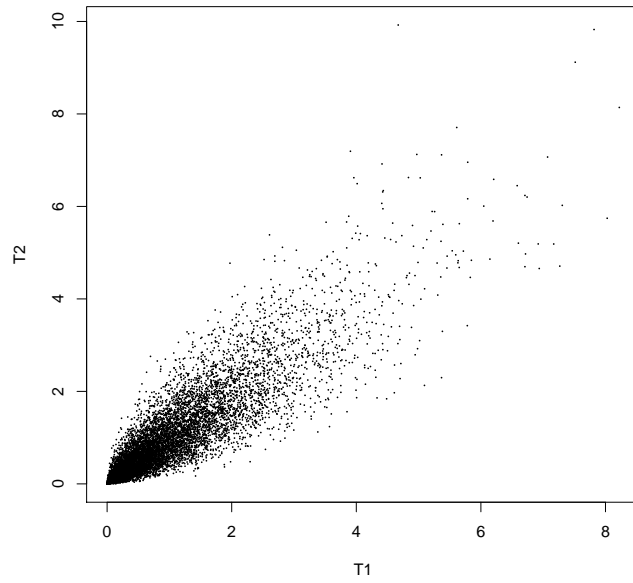

Figure 3: Scatter plot of T_1 vs T_2 with $\rho = 0.9$

The correlation estimate of T_1 and T_2 is
 $cor(T_1, T_2) = -0.6$ when $\rho = -0.9$ and
 $cor(T_1, T_2) = 0.88$ when $\rho = 0.9$

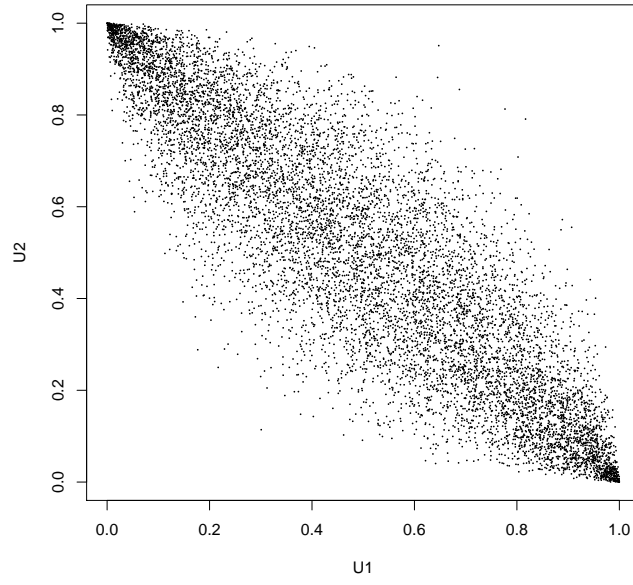

Figure 4: Scatter plot of U_1 vs U_2 with $\rho = -0.9$

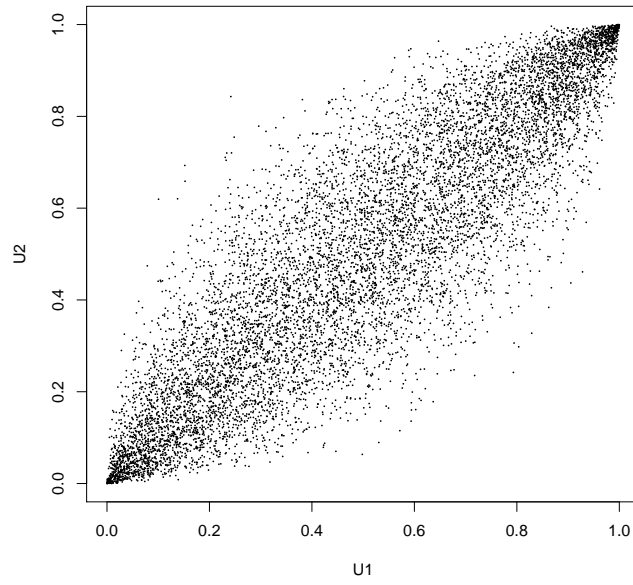

Figure 5: Scatter plot of U_1 vs U_2 with $\rho = 0.9$

c)

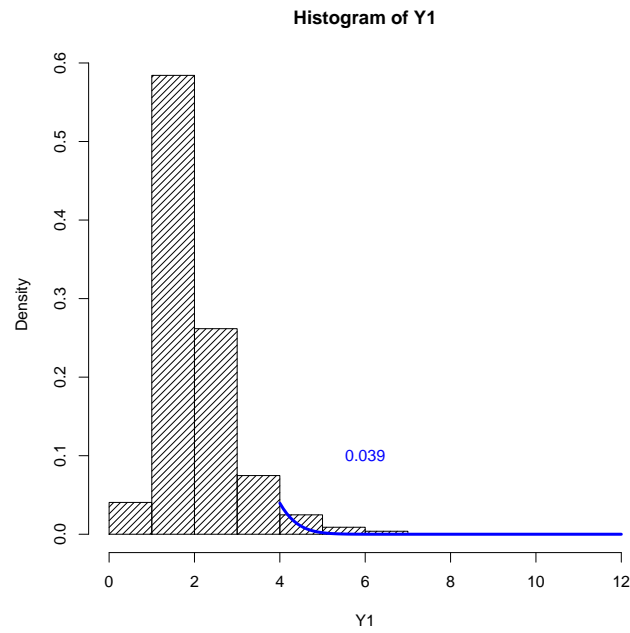

Figure 6: Histogram of $Y = T_1 + T_2$ with $\rho = -0,9$, $P(Y \geq 4) = 0.039$

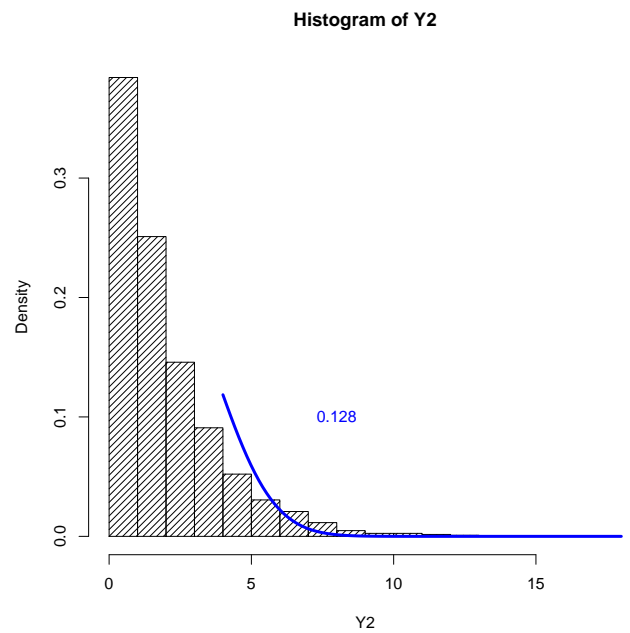

Figure 7: Histogram of $Y = T_1 + T_2$ with $\rho = 0,9$, $P(Y \geq 4) = 0.128$

d)

The estimate of $P(Y \geq 4) = 0.04$ when $\rho = -0.9$
and $= 0.131$ when $\rho = 0.9$ see Figure 6 and 7

mean(Y1>=4)/sqrt(n) #rho = -0.9
mean(Y2>=4)/sqrt(n) #rho = 0.9

>[1] 0.0019
 >[2] 0.0034

standard error is 0.0019 and 0.0034 for rho: -.9 and .9 respectively.

Corralation does not affect $E(Y) = E(T_1, T_2)$,

$cor(X, Y) = \frac{cov(X, Y)}{sd(X)sd(Y)}$ where $cov(X, Y) = E([X - E(X)][Y - E(Y)])$

ref [1] corralation is dependent on E(Y)
